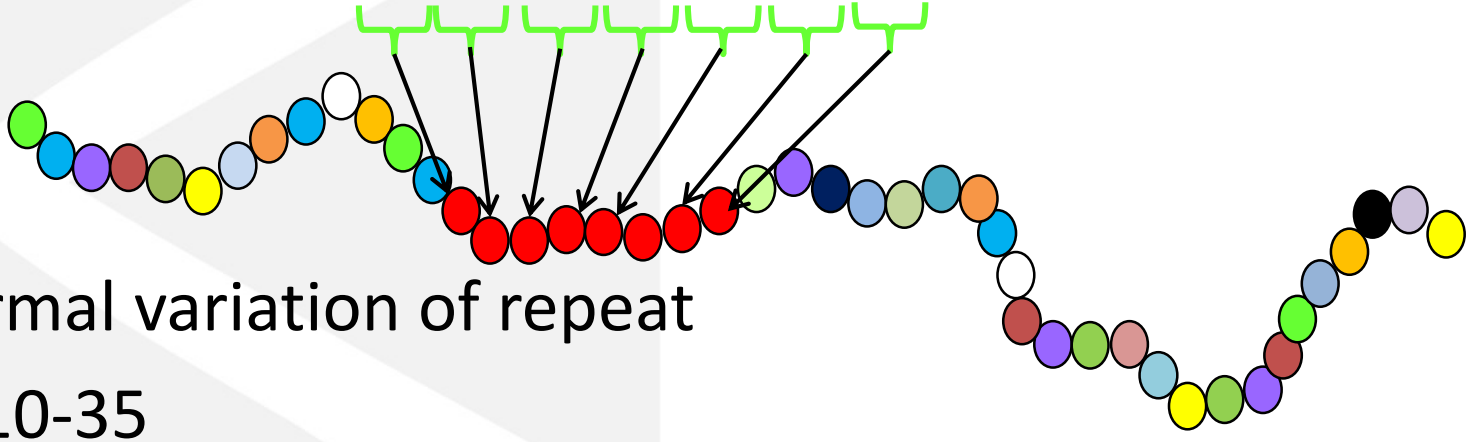
The Huntington Gene

- Gene is Huntingtin or *HTT*
- Triplet repeat or trinucleotide repeat

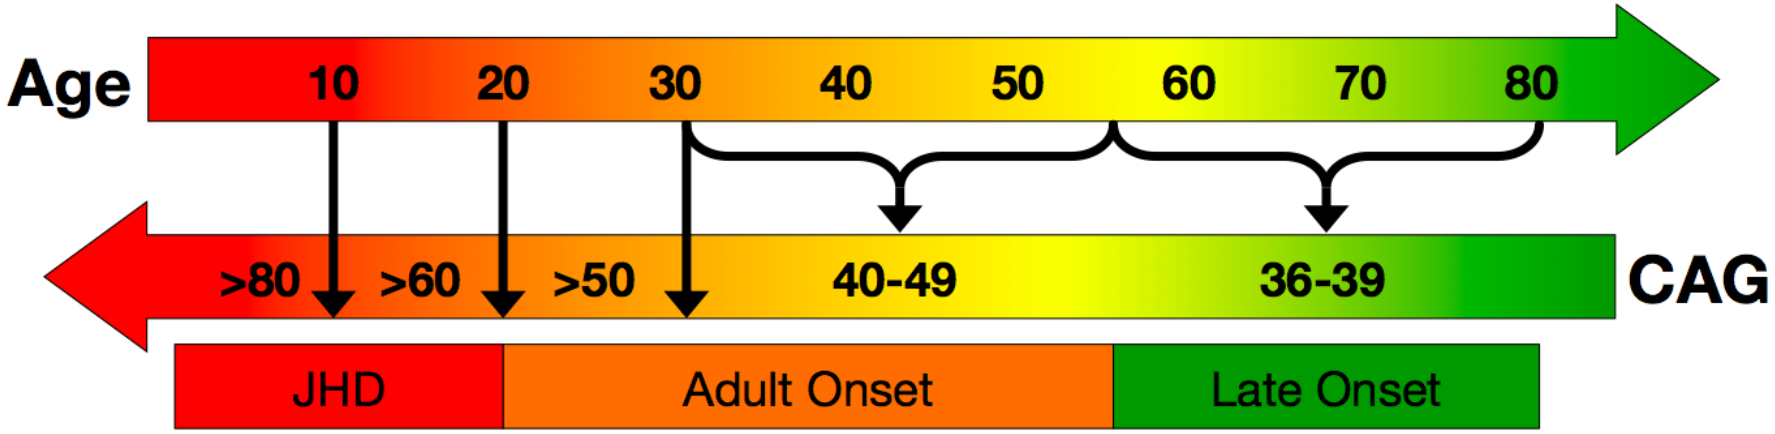
CGCCTAATCATGGCTCAGCAGCAGCAGCAGCAGCAGCAGGATATCCG



- Normal variation of repeat
  - 10-35
- >40, full penetration for disease
  - Mutant form = ***mHTT***

Huntington's Disease (HD)

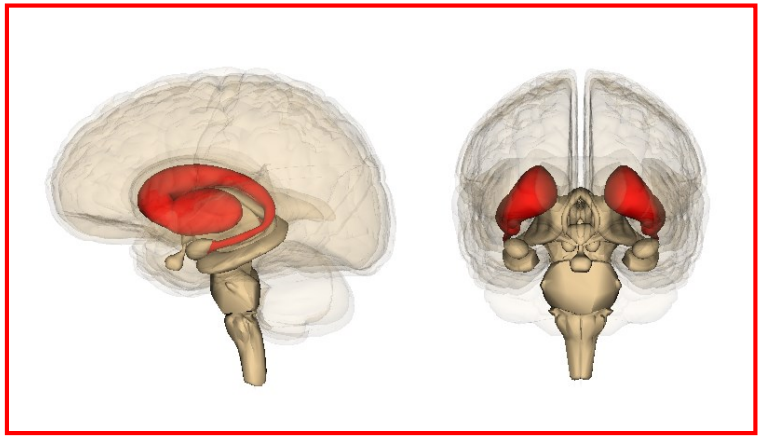
Longer CAG repeat → **earlier HD onset**



Longer repeat = more severe mutation

The Huntington Gene

- Since the discovery of the gene, many studies
- What have we learned?
- An important region of the brain called the **Striatum** is particularly affected in HD
- Large studies of individuals subjects like PREDICT and Track have shown that the striatum is affected YEARS before the onset of the disease



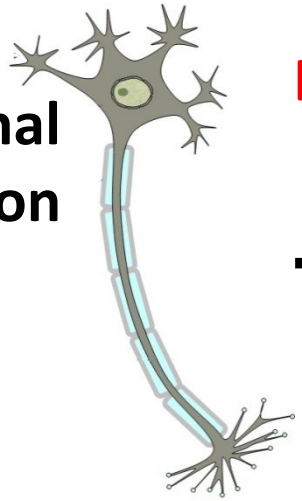
Questions that remain

- How far back does the abnormality in the striatum go? Is it possible that it didn't develop correctly?
- Why are there no symptoms until later in life even though the striatum is abnormal for years before that?
- We became interested in studying how the brain develops in people who have the expanded gene

Normal Neuron
Normal Development

Classical Concept: Gain of Function

Normal Neuron



Disease process
(toxic *mHTT*)

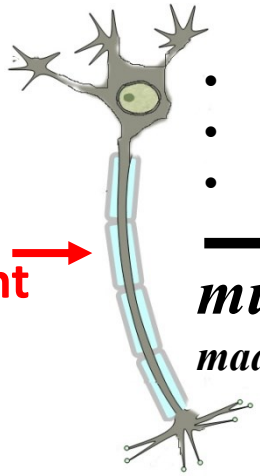
Degeneration

Cell Death

Mutant Neuron
Abnormal Development

Developmental Concept: Loss of Function

Disease process is abnormal development



- Maturational Processes
- Aging
- *mHTT*

mutant steady state
made possible by compensation

Degeneration

Cell Death

Kids-HD Program – Who is Eligible

- Subjects are children / young adults ages 6-25 years who
  - Have a parent (or grandparent)with HD (at-risk)
  - Healthy controls from the community=y
  - No symptoms of HD (no diagnosis of JHD)
- *For Research purposes only*, DNA from blood or saliva is used to measure CAG repeats in HTT; 2 groups:
  - Children at risk who are gene non-expanded (GNE)
  - Children at risk who are gene expanded (GE)

Kids-JHD Program – Who is Eligible

- Subjects are children / young adults ages 6-25 years who have already been diagnosed with JHD

Huntington's Disease Society of America

Kids HD + Kids JHD

They come to Iowa City

Huntington's Disease Society of America

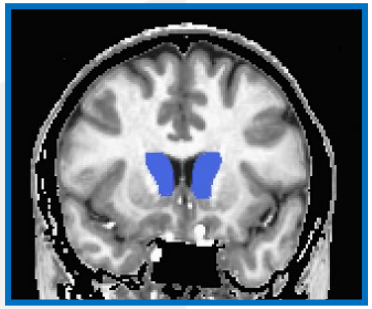
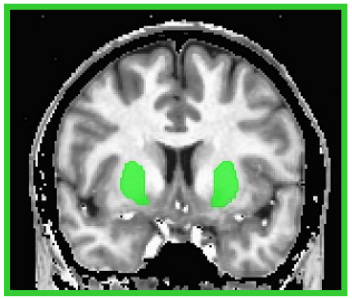
Kids-HD and Kids-JHD Programs

- Magnetic Resonance Imaging (MRI) allows us to take a picture of a person's brain
- We get volumes of specific brain regions
- We call this assessment of brain structure



Caudate



Putamen

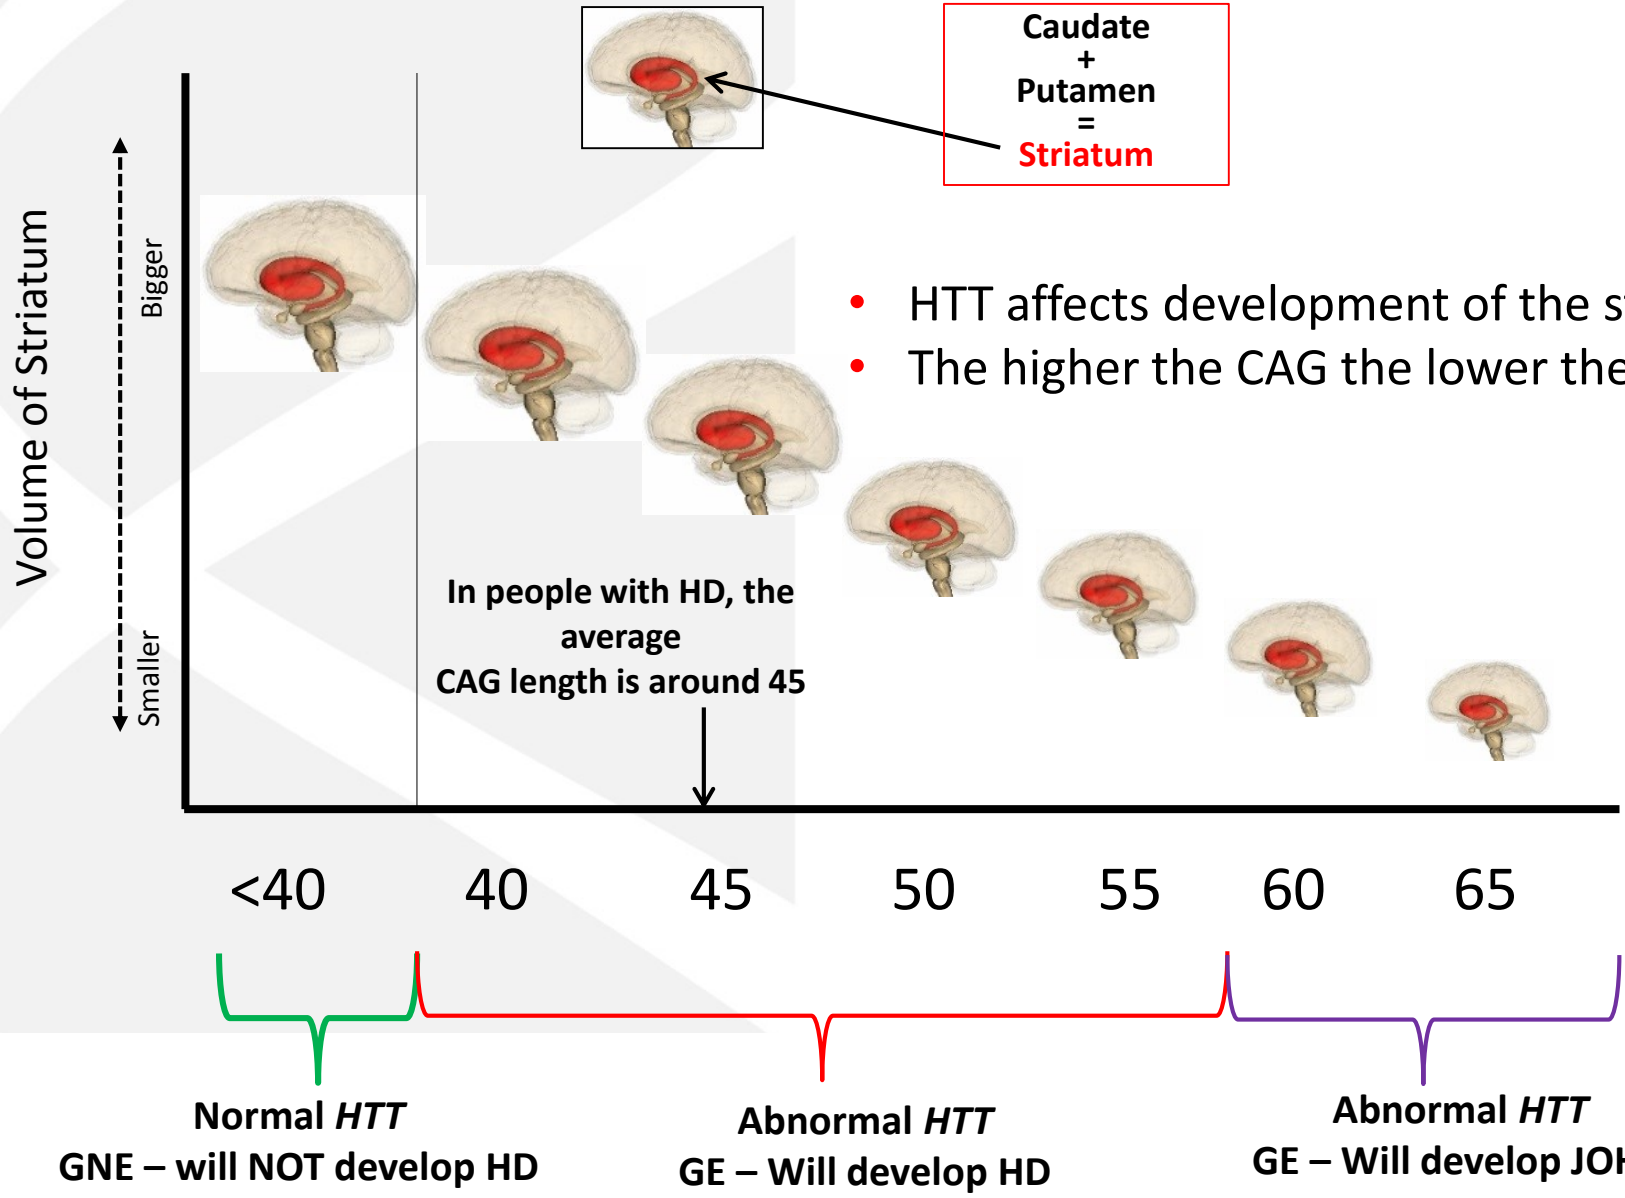
Effects of GE on Brain Development

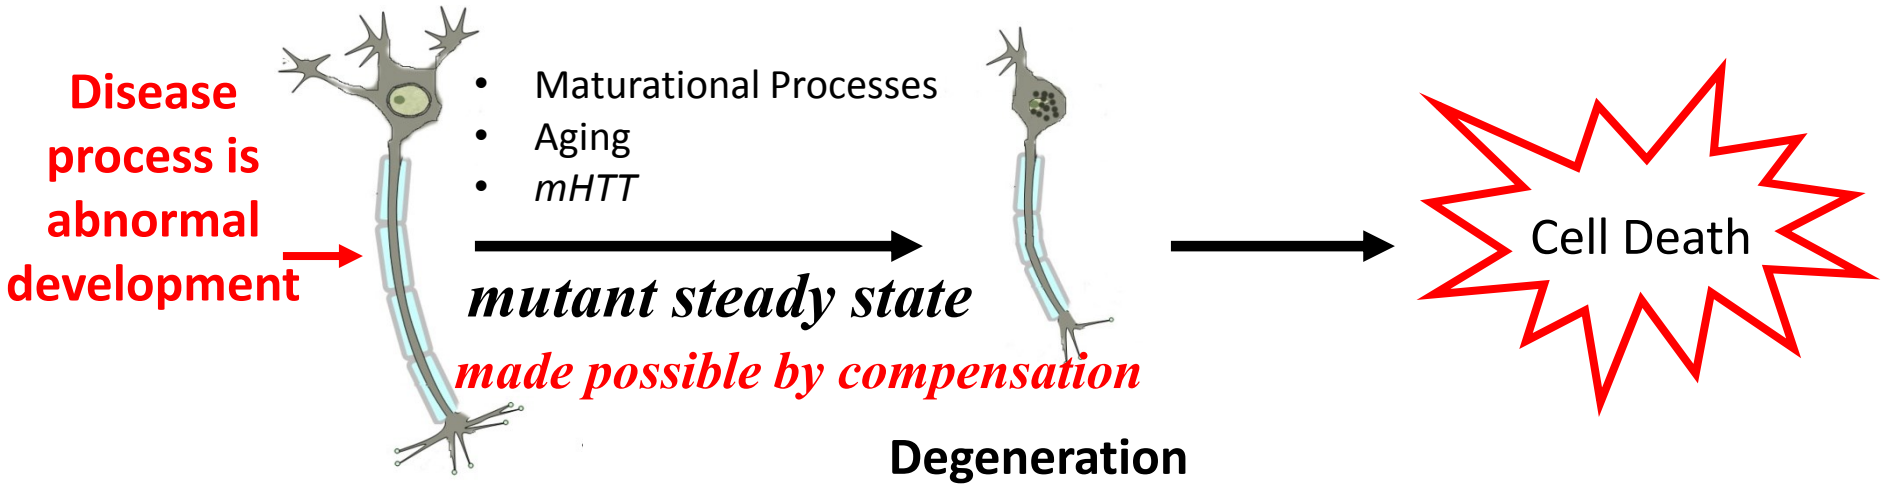


- HTT affects development of the striatum
- The higher the CAG the lower the volume

The Kids-HD Program

- So if the striatum is abnormal, why are these kids not having any symptoms?

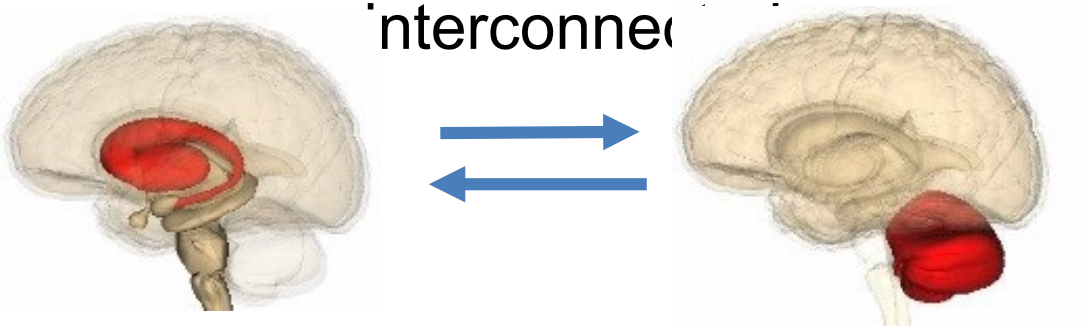
Developmental Concept: Loss of Function



What other parts of the brain might be responsible?
Invokes one of the most important advances in neuroscience: circuitry

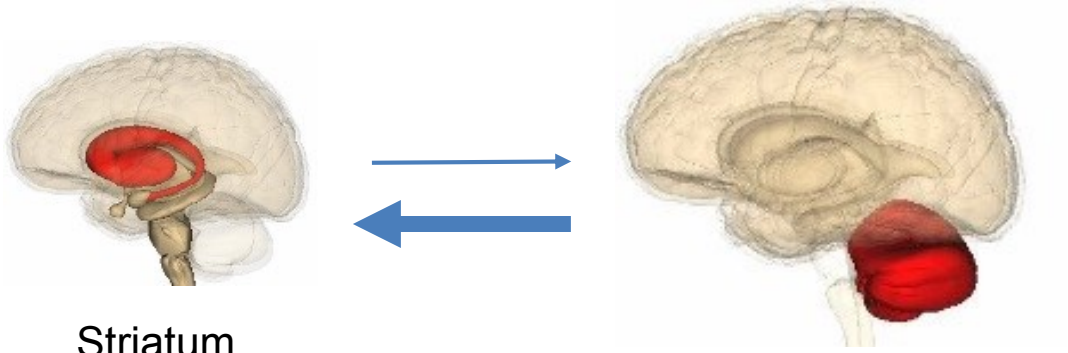
What happens when your striatum doesn't develop properly?

The Cerebellum and Striatum are interconnected



Striatum Cerebellum

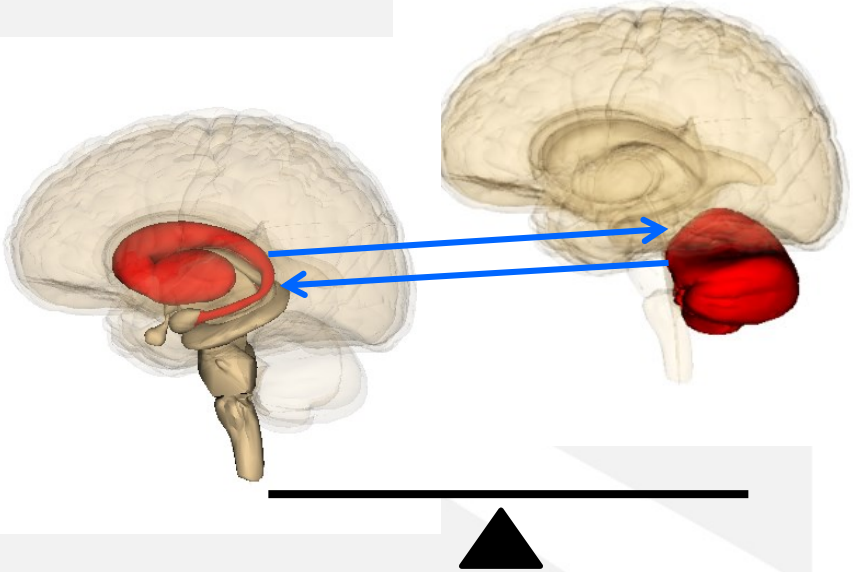
- They develop as a balanced circuit
- When one part is weak, the other part helps out or 'compensates'



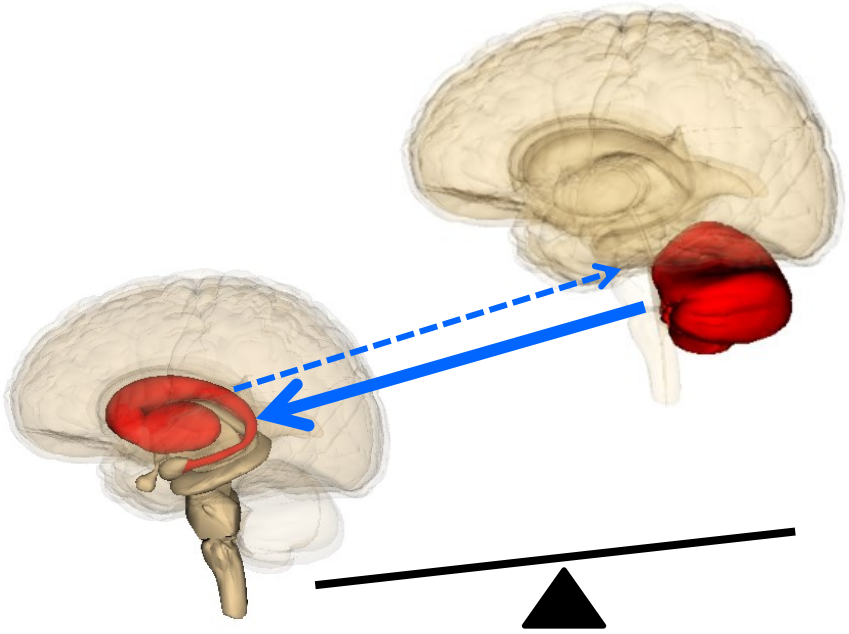
Striatum Cerebellum

Circuitry

- Theory – abnormal growth of the striatum is compensated for by the cerebellum



Normal Growth balanced circuit

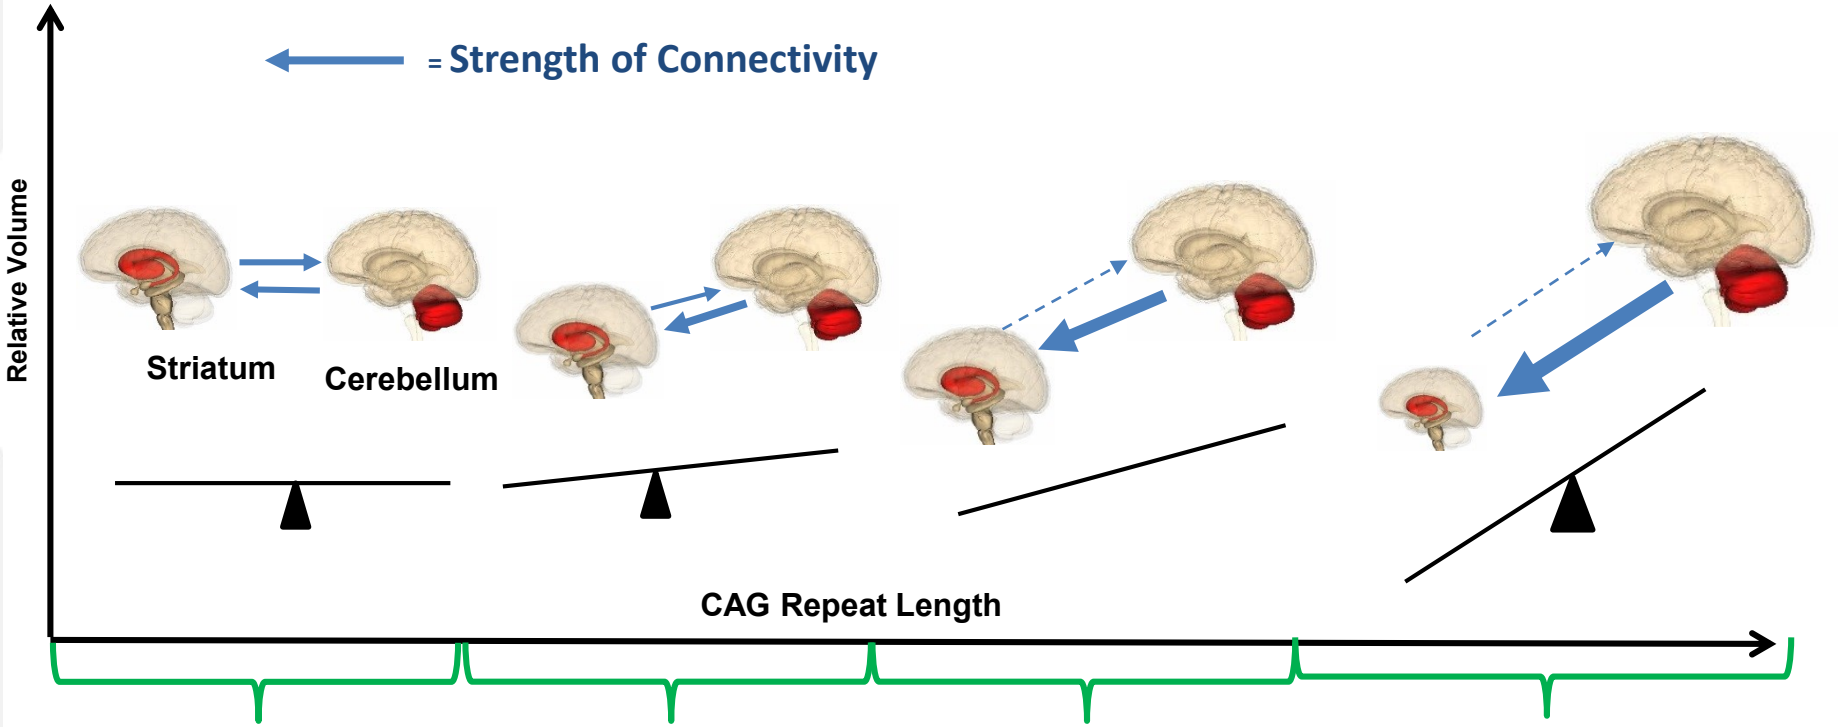


Abnormal growth, Cerebellar compensation

Circuitry

- Whhaaaa? The cerebellum involved in HD?
  - the one area of the brain discussed the least in all literature
  - considered to be ‘spared’ by HD disease pathology

Abnormal Development of Striatum



CAG = 10- 39

Normal Function

CAG = 40 – 44

Abnormal development with initial cerebellar compensation

CAG 40-44, well compensated; very subtle abnormalities in childhood

Adult onset of symptoms

CAG = 45 – 59

Abnormal development

Cerebellum doesn't compensate 100%

abnormalities in thinking and motor skills during childhood; the higher the CAG the worse the skills

Adult onset of symptoms, but earlier

CAG > 60 (JHD)

Severe abnormal development

cerebellum **<u>enlarged</u>**

Cerebellum instead of helping, is now 'over-active'

An over-active cerebellum leads to the hypokinetic symptoms of JHD (slowing, stiffness)

Juvenile Huntington's Disease

- Prevalence – How Common is it?
- Clinical features
- The diagnostic challenge

Juvenile Huntington's Disease

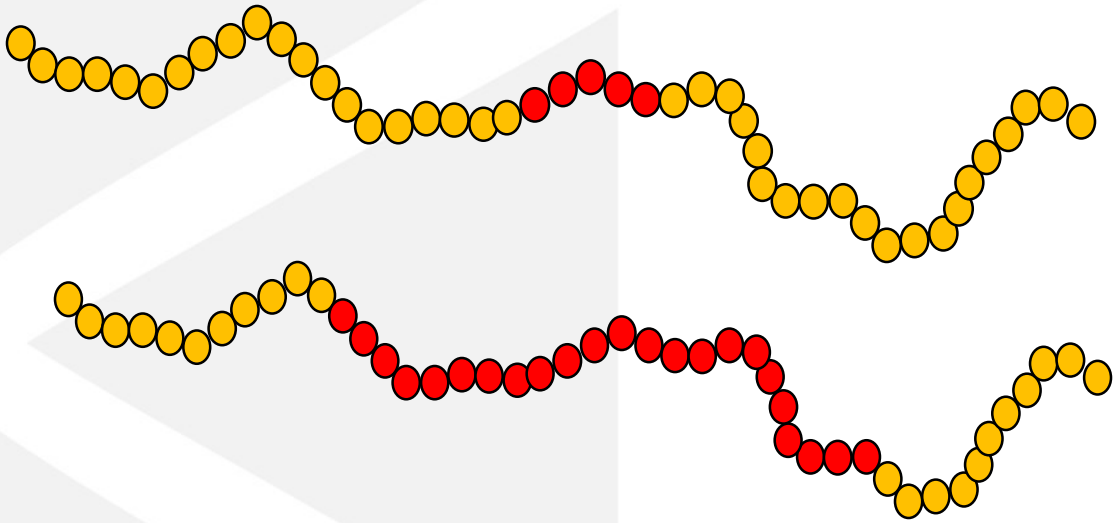
- Prevalence – How Common is it?
- Clinical features
- The diagnostic challenge

Juvenile Huntington's Disease

- Rare
  - Best estimate is around 5% of all HD cases
  - Even more rare for childhood onset

Genetic Anticipation

child, there is a chance it will expand



Example:
Parent
CAG = 43

Example:
Child
CAG = 65

- **This expansion is more likely to happen when the parent is MALE**
  - **Most JHD cases (up to 90%) have a father with HD**
  - **Converse – vast majority of fathers with HD will NOT have a child with JHD**

Juvenile Huntington's Disease

- Prevalence
- Clinical features
- The diagnostic challenge

Clinical Features

- Like all forms of HD, symptoms cluster in 3 main categories
  - Motor symptoms
  - Cognitive symptoms
  - Behavioral symptoms

Motor Symptoms

- Rigidity – stiff muscles
- Dystonia – muscles contract in abnormal position
- Ataxia – slow, shuffling, stooped walk
- Dysarthria – slurred speech
- Tremor
- Masked face – lack of movement in face
- Chorea – dance-like movements

Motor Symptoms

- These symptoms are often referred to as ‘Parkinsonian’ as they are similar to features of Parkinson’s disease.
- Chorea is much less common than is seen in adult onset HD, and often comes later in the disease

Cognitive Symptoms

  - Everything from general intelligence (IQ) to specific functions such as memory, attention, language and visuospatial skills

- For children with childhood onset (before the age of 10), this may be a failure of thinking skills development
- For JHD it is often seen as declining school or academic performance
- Like Adult onset, these thinking skills deficits will progress over time

Behavioral / Psychiatric Symptoms

- Behavior can be divided into 2 main categories:
  - Externalizing Behaviors – behavior that other people can see
    - Hyperactivity
    - Inattention
    - Opposition (not wanting to follow rules, talking back)
    - Aggression
  - Internalizing Behaviors – what people feel inside
    - Sad or depressed
    - Anxious
    - Obsessions

Behavioral /Psychiatric Symptoms

- Externalizing – the most common
  - Attention Deficit Hyperactivity Disorder (ADHD) may be diagnosed
  - Aggression may come on quickly, with unclear triggers
- Psychosis: hallucinations and delusions
    - More common in onset in teens and 20's

Presenting Symptoms

- In a large study of 53 cases *(Siesling et al.)*
  - 70% presented with Behavior symptoms
  - 48% with motor symptoms
  - 27% with cognitive symptoms
  - During the course, the number of cases that experienced behavioral disturbances:
    - Males: 93%
    - Females: 81%

Other Accompanying Features

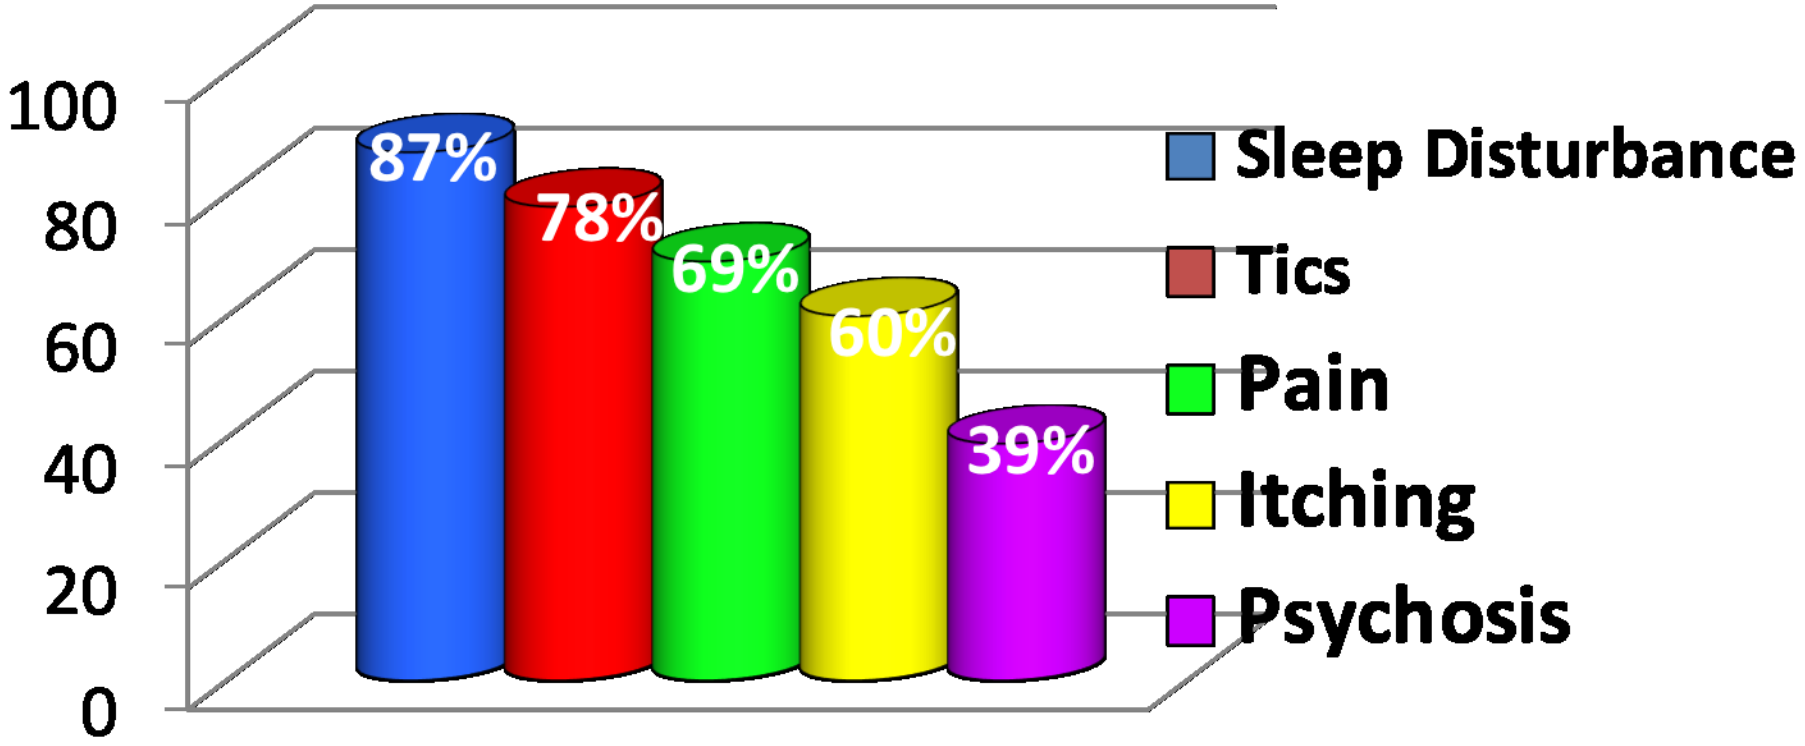
- Seizures
  - Up to 30-40% of cases
    - Generalized or tonic-clonic - ‘’grand mal”
      - Lose consciousness; entire brain involved
    - Partial complex
      - Impaired consciousness; parts of the brain involved
    - myoclonic epilepsy
      - Muscle jerks, no impairment of consciousness
  - Tend to be more common in the earliest onset cases and can be a presenting symptom

Common but unrecognized

- Through social media, we administered a survey designed to quantify identified symptoms often mentioned by JHD caretakers, but not part of the classic triad motor, cognitive, behavioral symptoms
    1. **Sleep Disturbance**
    2. **Pain**
    3. **‘Itching’**
    4. **Tics**
    5. **Psychosis**

Common but unrecognized

Demographic Info N=33	Mean	Range
Age at Diagnosis (yr)	12.21	3-21
Current Age (years)	15.75	4-27



Duration of Disease

- Somewhat controversial
- Duration of disease in JHD does NOT seem to be any different than duration of disease in adult onset
  - Average 15-20 years from diagnosis to death
- Thus even though CAG repeat can predict age of onset, it does NOT seem to predict duration of disease

Juvenile Huntington's Disease

- Prevalence
- Clinical features
- The diagnostic challenge

Juvenile Huntington's Disease

- Onset
  - The presence of unmistakable (not subtle) neurologic (**motor**) signs

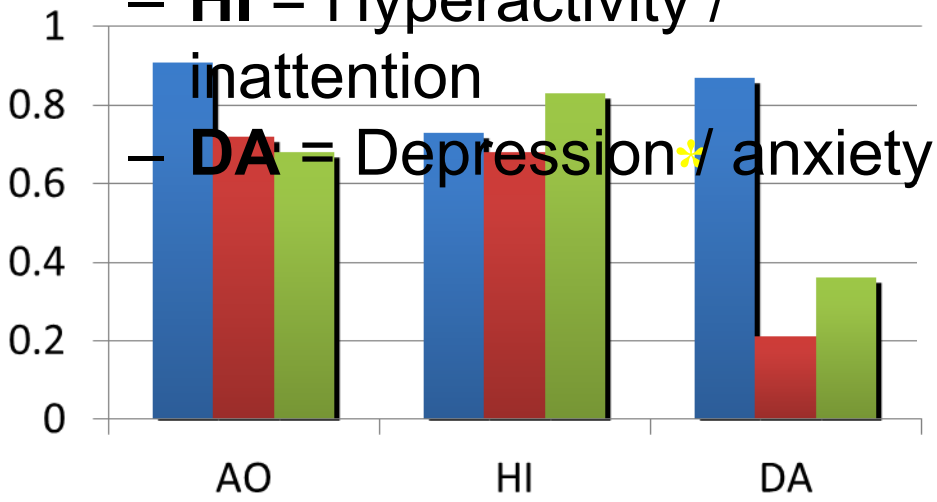
The Diagnostic Challenge

- Average length of time from first symptom to diagnosis – NINE YEARS *(Ribai et al)*
- *Most common presenting symptom is behavior

Behavior is a non-specific symptom

- Data from Kids-HD study
- Parent ratings of behavior
  - **AO** = aggression / opposition
  - **HI** = Hyperactivity / inattention
  - **DA** = Depression / anxiety

The higher the score, the worse the behavior



GNE = at risk, Gene Non-Expanded

GE = at risk, Gene Expanded SHORT CAG 40-49

GE = at risk, Gene Expanded LONG CAG 50-73

- Behavior does NOT distinguish groups
  - Exception being more depression in the gene non-expanded group

The Diagnostic Challenge

- What is the risk of getting a genetic test based on a non-specific symptom?
  - That symptom may not be related to HD
  - Analogy – making diagnosis of pneumonia for every patient that presents with a cough
- Example, child with ADHD
  - Genetic test: CAG=43
  - What if motor symptoms do not develop
    - And behavioral symptoms ameliorate
    - May have gotten ‘presymptomatic’ testing on a child who did not have the chance to make that decision for themselves

Can MRI imaging help the diagnosis of JHD?

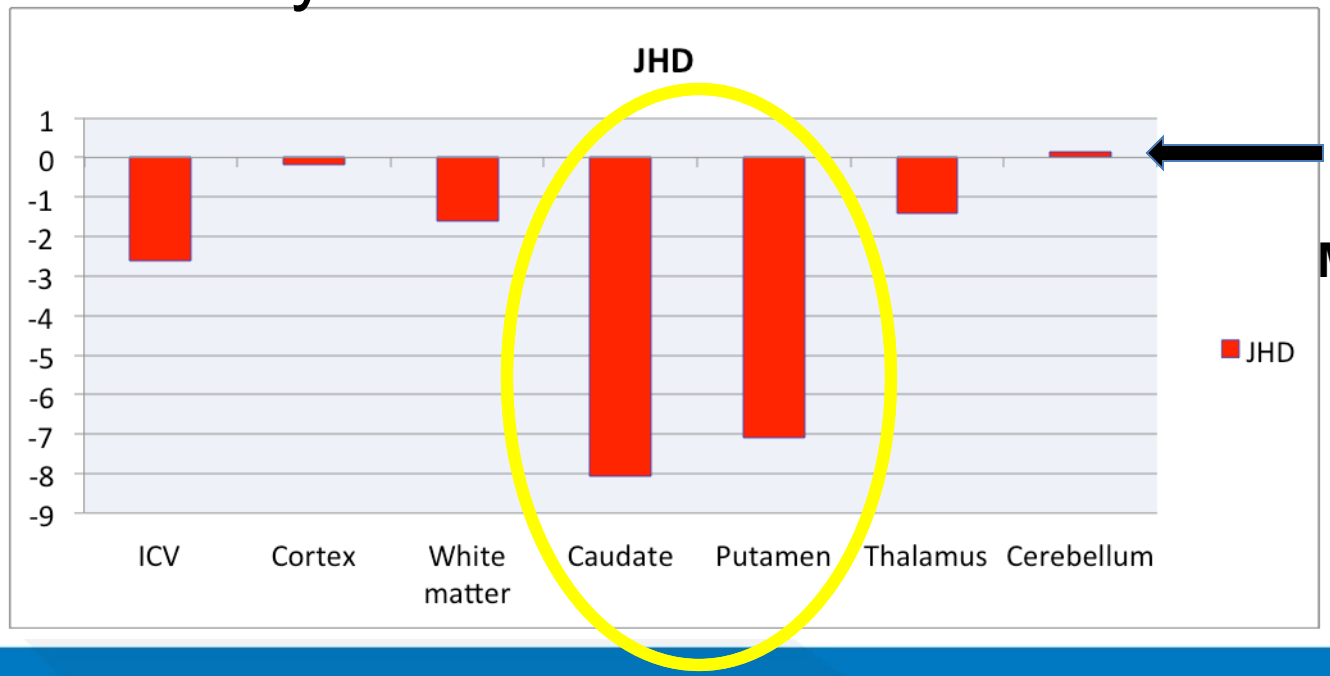
- Here are 5 Seven year old females
- Which one has JHD, age onset 6, CAG 101?

A 'clinical' scan, read by a radiologist – qualitative assessment: does this brain 'look' different?

No – this will not help diagnosis

QUANTITATIVE MRI

- Computer program calculates volumes
- JHD case compared to 7 age matched females, healthy controls



Healthy Control Mean = 0
